Abstract

Techniques traditionally used in the study of the existence of solutions of nonlinear differential equations has recently been used to solve problems of control, state estimation and parameter identification of nonlinear systems. These techniques often require some topological adjustments of either the space of admissible input functions $U$ (the control space) or the state space $X$ of the system which became possible with the use of matched sets introduced by the author in [1,2]. The present work places its emphasis on how the matched sets can be used to adjust the spaces $U$ and $X$ for the problem of nonlinear control as formulated below. A summary of the theory of complete matched sets is also shown. Moreover, the semigroup approach is used so that the distributed parameter systems and delay systems can be considered as well as lumped parameter systems.

Keywords: Control, state space, nonlinear systems, distributed parameter systems, lumped parameter systems.

1 Introduction

Some techniques traditionally used in the study of the existence of solutions of nonlinear differential equations has been extended to solve problems of control, state estimation and parameter identification of nonlinear systems (see [3,4,5] and also [6]). Here we consider systems of the type:

$$\dot{x} = Ax(t) + N(x(t)) + Bu(t),$$

$$x(0) = x_0 \in X$$

where $A$ is a linear operator on an appropriate Hilbert space $X$ (the state space), $N$ is a nonlinear operator from an input space $U$ to $X$, and $u(\cdot) \in U$ is the control ($U$ being a space of functions from the interval $[0,T]$ to the input space $U$ of the system). Such systems are often called semilinear systems.

It is assumed that the dynamics of the autonomous part of the system (1), i.e.,

$$\dot{x} = Ax(t), x(0) = x_0 \in X$$

can be described in terms of a strongly continuous semigroup $S(t)$ on $X$, so that the above formulation includes distributed parameter systems and delay systems, as well as lumped parameter systems.

2 The Control Problem

Clearly for the case of lumped parameter systems we have that $A$ is an $n \times n$ matrix, $X = \mathbb{R}^n$ and the semigroup $S(t)$ becomes

$$S(t) = e^{At}$$

The problem of control is to find a control $u(\cdot)$ which drives system (1) from the initial state $x_0 \in X$ to a given desired final state $x_d \in X$ at $t = T$. System (1) may be derived from the linearization of a system described by a nonlinear evolution equation such as:

$$\dot{x} = f(x,u,t), x(0) = x_0.$$  (2)

Equation (1) is to be interpreted in the mild sense:

$$x(t) = S(t)x_0 + \int_0^t S(t-\tau)N x(\tau) d\tau + \int_0^t S(t-\tau)B u(\tau) d\tau$$  (3)

with the initial conditions

$$x(0) = x_0 \in X.$$

Papers such as [3,5], and also [7] presented some techniques to solve the above nonlinear control problem (2) using the fixed point of a map $\Phi : X \to X$ constructed on a space $X$ of trajectories $x(\cdot)$ (e.g., $X = L^2(0,T; \mathbb{R})$). These techniques often assume that the control space $U$ and/or the state space $X$ can be adjusted to new spaces $U'$ and $X'$, (with both $U \cap U'$ and $X \cap X'$ dense on their counterparts $U$ and $X$ respectively) in order to the Volterra type operator $G$ (defined on $U$) associated with the nonlinear control problem in its mild form (3)

$$(Gu(\cdot))(t) = \int_0^t S(t-\tau)Bu(\tau) d\tau$$  (4)

have closed range in the space of trajectories $X$.

Sometimes however the assumption is that $G_T$ (also defined on $U$) given by
have closed range in the state space $X$. Besides, if $L$ (defined on $X$) is the linear operator
\[
L(t)x(t) = \int_0^t S(t, \tau)x(\tau)d\tau,
\]
the range of the operator $G$ should be large enough to incorporates the set of nonlinear values $L(t)Nz(\cdot)$, for all $t \in [0, T]$, that is
\[
\text{Range} (G) \supseteq \{L(t)Nz(\cdot) : t \in [0, T]\}
\]
For simple cases (e.g., $U = L^2(0, T; X)$ and $X = L^2(0,1)$) these adjustments were not difficult to be done [7]. However, this is not always the case. Here we present some results based on matched sets which shows that such adjustments are always possible. Actually, this is part of a more comprehensive theory developed in [1] which shows that if $E_1$ and $E_2$ are inner product spaces and $\Psi$: $E_1 \rightarrow E_2$ is a densely defined linear operator, then the topology of $E_1$ and/or $E_2$ can always be adjusted such that some topological properties of $\Psi$ (such as boundedness or continuity, compactness, closed range, etc.) will hold.

In other words, the spaces $U$ of input control functions and/or the space of trajectories $X$ can be adjusted to new spaces $U'$ and $X'$ (with $U \cap U'$ and $X \cap X'$ dense on their original counterparts $U$ and $X$ respectively) in order to some Volterra-type operators, such as $G$ in (4), associated with the nonlinear control problem (3) have closed range.

Similarly, when the state space $X$ is infinite dimensional, the above adjustment can be done for $U$ and $X$ to obtain closed range for $G_T$ in (5).

Also, in the problem of state estimation of infinite dimensional systems using fixed point techniques is often assumed [3, 7] that the state space $X$ and/or the state of output functions $Y$ can be adjusted to new spaces $X'$ and $Y'$ (with $X \cap X'$ and $Y \cap Y'$ dense on their original counterparts $X$ and $Y$ respectively) in order to some Volterra-type operators (associated with the state estimation problem) have closed range.

3 The Adjustments

Here we present some results based on matched sets which shows that such adjustments are always possible. Actually this is part of a comprehensive theory [1, 2] which shows that if $U$ and $X$ are inner-product spaces and $G$: $U \rightarrow X$ is a densely defined linear operator then the topology of $U$ and/or $X$ can always be adjusted such that some topological properties of $G$ (such as boundedness or continuity, compactness, closed range, etc.) will hold. The new adjusted spaces $U'$ and $X'$ will have the form:

\[
U' = \left\{ u = \sum_{n \in \Gamma} u_n e_n : \left( \sum_{n \in \Gamma} \alpha_n |u_n|^2 \right)^{1/2} < \infty \right\}
\]

with the topology on $U'$ given by the norm
\[
\|u\|_{U'} = \left( \sum_{n \in \Gamma} \alpha_n |u_n|^2 \right)^{1/2}
\]

and
\[
X' = \left\{ x = \sum_{n \in \Lambda} x_n \phi_n : \left( \sum_{n \in \Lambda} \beta_n |x_n|^2 \right)^{1/2} < \infty \right\}
\]

with the topology on $X'$ given by the norm
\[
\|x\|_{X'} = \left( \sum_{n \in \Lambda} \beta_n |x_n|^2 \right)^{1/2}
\]

where $u_n \cdot x_n \in F = R$ or $C$; $\alpha_n \beta_n$ are real numbers satisfying
\[
\alpha_n > 0 \quad \text{for all } n \in \Gamma,
\]
\[
\beta_n > 0 \quad \text{for all } n \in \Lambda,
\]

and
\[
M = \left\{ (e_n)_{n \in \Gamma}, (\phi_n)_{n \in \Lambda}, \Delta, \Gamma, \Lambda \right\}
\]

is any complete matched set for the operator $G$.

3.1 Matched Sets

A matched set $M$ is a quintuple of the type above (Eq. (8)), consisting of two sequences
\[
\{e_n\}_{n \in \Gamma} \quad \text{and} \quad \{\phi_n\}_{n \in \Lambda}
\]

and three countable sets $\Delta$, $\Gamma$ and $\Lambda$ satisfying:
\[
e_n \in U \quad \text{for all } n \in \Gamma,
\]
\[
\phi_n \in X \quad \text{for all } n \in \Lambda,
\]
\[
\Delta \subseteq \Gamma \cap \Lambda \quad \text{and} \quad \Lambda \text{ non empty.}
\]

Moreover, the following must also hold in order to $M$ to be a matched set for the linear operator $G$
\[
G e_n = \phi_n \quad \text{for all } n \in \Delta,
\]
\[
G \Phi_\Delta = 0 \quad \text{for all } n \in \Gamma \setminus \Lambda.
\]

A matched set $M$ is said to be complete if
\[
\text{Span}\{e_n\}_{n \in \Gamma} = U
\]

and
\[
\text{Span}\{\phi_n\}_{n \in \Lambda} = X
\]

where the bars represent the closure of the spaces.

3.2 The Generation of Matched Sets

There are two different methods for obtaining a complete matched set $M$ for a linear operator $G$. In the
4.1 The Null Space and the Range of G

Other spaces and operator related with G can be expressed in a similar way by using again the sequences \( \{e_n\}_{n \in \Gamma} \) and \( \{\phi_n\}_{n \in \Lambda} \) from the matched set. For example: the closures of both the Null space of G, \( \text{Null}(G) \), and Range of G, \( \text{Range}(G) \), are given respectively by

\[
\text{Null}(G) = \left\{ u = \sum_{n \in \Gamma} u_n e_n : \sum_{n \in \Gamma} |u_n|^2 < \infty \right\}
\]

and

\[
\text{Range}(G) = \left\{ x = \sum_{n \in \Lambda} x_n \phi_n : \sum_{n \in \Lambda} |x_n|^2 < \infty \right\}
\]

4.2 Projections

The orthogonal projections \( P : U' \to U' \) onto the space \( \text{Null}(G) \) and \( P : X' \to X' \) onto \( \text{Range}(G) \) are given respectively by

\[
P_u = \sum_{n \in \Delta} u_n e_n
\]

and

\[
P_x = \sum_{n \in \Delta} x_n \phi_n
\]

4.3 The Adjoint Operator of G

The adjoint operator of G, \( G^* : D(G) \to U' \) is given by

\[
G^* x = \sum_{n \in \Delta} \beta_n x_n e_n
\]

with domain given by

\[
D(G^*) = \left\{ x = \sum_{n \in \Lambda} x_n \phi_n : \sum_{n \in \Lambda} |x_n|^2 < \infty \right\}
\]

4.4 The Pseudo-inverse of G

The generalised inverse (or pseudo-inverse) of G, that is \( G^+ : D(G^+) \to U' \) is given by

\[
G^+ x = \sum_{n \in \Delta} \beta_n x_n e_n
\]

with domain given by

\[
D(G^+) = \left\{ x = \sum_{n \in \Lambda} x_n \phi_n : \sum_{n \in \Lambda} |x_n|^2 < \infty \right\}
\]

If we set \( \alpha_n = \|e_n\|^2 \) for all \( n \in \Gamma \), then \( U' \cong U \) (or at least \( U' \approx U \), i.e., \( U' \) is topologically isomorphic to \( U \)) and similarly, if we set \( \beta_n = \|\phi_n\|^2 \) for all \( n \in \Lambda \), then \( X' \cong X \) (or at least \( X' \approx X \), i.e., \( X' \) is topologically isomorphic to \( X \)). However, a different choice of \( \alpha_n \) will change the topology of \( U \) to a new space \( U' \) (with \( U \cap U' \) dense on \( U \)) as well as a different choice of \( \beta_n \) will change the topology of \( X \) to a new space \( X' \) (with \( X \cap X' \) dense on \( X \)).

5 The Rules for the Adjustments

Here is where we establish the relationship between \( \alpha_n \) and \( \beta_n \) such that the operator \( G : U' \to X' \) hold some desired topological properties. The following results can be proved:

5.1 Boundedness
G: $\mathbf{U}' \to \mathbf{X}'$ is a bounded operator if and only if the set
\[
\begin{bmatrix}
\beta_n \\
\alpha_n
\end{bmatrix}_{n \in \Lambda}
\]
is bounded. \hspace{1cm} (9)

5.2 Closed Range
G: $\mathbf{U}' \to \mathbf{X}'$ has closed range in $\mathbf{X}'$ if and only if the set
\[
\begin{bmatrix}
\beta_n \\
\alpha_n
\end{bmatrix}_{n \in \Lambda}
\]
is bounded. \hspace{1cm} (10)

5.3 Compactness
G: $\mathbf{U}' \to \mathbf{X}'$ is a Hilbert-Schmidt operator if and only if
\[
\sum_{n \in \Lambda} \left( \frac{\beta_n}{\alpha_n} \right) < \infty
\]
Clearly if G is a Hilbert-Schmidt operator then G is a compact (or completely continuous) operator. The above results on matched sets provide the rules for the adjustment of the spaces $\mathbf{U}$ and $\mathbf{X}$.

6 Example
For instance, let us consider the semilinear (non-stable) system
\[
\frac{d^2 y}{dt^2} - 2 \frac{dy}{dt} + y(t) + N(y, \frac{dy}{dt}) = u(t),
\]
where $N$ is the nonlinearity such as for example:
\[
N(y, \dot{y}) = \sqrt{y} \dot{y},
\]
or
\[
N(y, \dot{y}) = y \dot{y}^2.
\]
This system can easily be re-written in the state space form (1) as:
\[
\begin{bmatrix}
2 & -1 \\
1 & 0
\end{bmatrix} \begin{bmatrix} x \end{bmatrix}(t) + \begin{bmatrix} 1 \\
0 \end{bmatrix} u(t) - \begin{bmatrix} N(x_1, x_2) \\
0
\end{bmatrix}
\]
\[
x_0 = \begin{bmatrix} x_{01} \\
x_{02}
\end{bmatrix} = \begin{bmatrix} \dot{y}(0) \\
y(0)
\end{bmatrix}
\]
where $\mathbf{x} = \begin{bmatrix} x_1 \\
x_2
\end{bmatrix}$, $x_1 = \dot{y}$ and $x_2 = y$. So, the output equation, if necessary, is:
\[
y(t) = \begin{bmatrix} 0 & 1
\end{bmatrix} \mathbf{x}(t).
\]
Here the semigroup $S(t)$ is given by
\[
S(t) = e^{At} = \begin{bmatrix} (1 + t)e^t & -te^t \\
te^t & (1 - t)e^t
\end{bmatrix},
\]
and therefore, the state $\mathbf{x}(t)$ can be expressed in the form (3) by
\[
\mathbf{x}(t) = \begin{bmatrix} (1 + t)e^t x_{01} - te^t x_{02} \\
te^t x_{01} + (1 - t)e^t x_{02}
\end{bmatrix} + (G \mathbf{u}(\cdot) \mathbf{t}) + \int_0^1 \begin{bmatrix} (1 + t - \tau)e^{-\tau} \\
(1 - \tau)e^{-\tau}
\end{bmatrix} N(x_1, x_2)d\tau
\]
where the operator $G$ from $\mathbf{U}$ to some space of functions (trajectories) $\mathbf{x}(\cdot):[0,T] \to \mathbf{X} = \mathbb{R}^2$ is given by
\[
(G \mathbf{u}(\cdot) \mathbf{t}) = \int_0^1 \begin{bmatrix} (1 + t - \tau)e^{-\tau} \\
(1 - \tau)e^{-\tau}
\end{bmatrix} \mathbf{u}(\tau)d\tau.
\]
Let us assume that the space $\mathbf{U}$ of input functions is $L^2(0,T)$ for some $T > 0$. Here the Range $(G \mathbf{t})$ is always closed since it has finite dimension ($\mathbf{X} = \mathbb{R}^2$). Even though the Range $(G)$ is a space of functions from $[0,T]$ to $\mathbf{X}$ and its topology can be adjusted in order to be closed.

We can let $\{e_n(\cdot)\}_{n \in \Gamma}$ be any complete orthonormal set in $L^2(0,T)$, such as for example:
\[
\Gamma = N = \{1, 2, \ldots\}
\]
and the space of input controls $\mathbf{U}'$ as defined in (6). Now, if we set $q_n = 1$, for $n = 1, 2, \ldots$, the space of input controls $\mathbf{U}$ becomes $\mathbf{U}'$ defined in (6). With this choice we have $\mathbf{U} \approx \mathbf{U}' = L^2(0,T)$.

However, by a different choice of $q_n$'s we could give $\mathbf{U}'$ a different topology in order to be either larger or smoother than $L^2(0,T)$. If $q_n \leq 1$ for all $n = 1, 2, \ldots$, (or for all $n > n_0$, for some finite $n_0 \in \mathbb{N}$), then $\mathbf{U}'$ will be a space of smoother functions. For example, if
\[
q_n = \frac{n^2 \pi^2}{T^2}, \hspace{1cm} n = 1, 2, \ldots
\]
then $\mathbf{U} \approx H^1_0(0,T)$ the Sobolev space of differentiable functions on $[0,T]$.

On the other hand, by setting $q_n \leq 1$ for all $n = 1, 2, \ldots$, (or for all $n > n_0$, $n \in \mathbb{N}$, for some finite $n_0 \in \mathbb{N}$), then $\mathbf{U}'$ will be a larger space of functions than $L^2(0,T)$. For example, if
\[
q_n = \frac{T^2}{n^2 \pi^2}, n = 1, 2, \ldots
\]
then $\mathbf{U} \approx H^{-1}(0,T)$ the Sobolev space (distributions). Now set $\Delta = \Lambda = \Gamma = N = \{1, 2, \ldots\}$, $\phi_n(\cdot)$ as...
\[
\phi_n(t) = (G_n(t)) = \left(\phi_{n1}(t), \phi_{n2}(t)\right) \in \mathbb{R}^2
\]

where

\[
\begin{align*}
\phi_{n1}(t) &= \int_0^t (1+t-\tau)e^{\tau t} \left(\frac{2}{T} \sin \frac{\pi \tau}{T} \right) d\tau \\
\phi_{n2}(t) &= \int_0^t (t-\tau)e^{\tau t} \left(\frac{2}{T} \sin \frac{\pi \tau}{T} \right) d\tau
\end{align*}
\]

and the space of trajectories \(X'\) as defined in (7).

To give \(X\) the same topology as a known space such as, for example, \(L^2(0,T;\mathbb{R}^2)\), (that is, \(X' \approx L^2(0,T;\mathbb{R}^2)\)) we then have to set

\[
\beta_n = \left\|\phi_n\right\|_{L^2(0,T;\mathbb{R}^2)} \quad \text{for} \ n = 1, 2, ... \quad (14)
\]

However, some nonlinearities such as in the one in (12) may force us to work in larger spaces and therefore we have to choose different values for the constants \(\beta_n\)'s. They will have to be smaller than the ones chosen in Eq (14) above. In that case, in order to have the Range of the operator \(G\) closed (i.e., \(\text{Range } (G)\) closed), we will also have to choose different \(\alpha_n\)'s. Actually, from Eq (10) we know that \(\alpha_n\), for \(n=1, 2, ...\) must be chosen such that the set

\[
\{\alpha_n / \beta_n\}_{n=1,2, ...}
\]

is bounded. For instance, \(\alpha_n = \beta_n\), for \(n = 1, 2, ...\)

Some nonlinearities however, such as the one in (13), allow us to work on smoother state spaces \(X\). In this case we can also give a smoother topology to both \(X'\) and \(U'\) by an adequate choice of the \(\beta_n\)'s and the \(\alpha_n\)'s, respectively.

Now the constants \(\beta_n\)'s will have to be greater than the ones chosen in Eq (14) above.

7 Conclusion

Here we presented results that provide the rules for the topological adjustment of the spaces \(U\) (the control space) and \(X\) (the space of trajectories) and for the adjustment of the spaces \(U\) and \(X\) (the state space). If \(G: U \rightarrow X\) does not satisfy a desired topological property (e.g., boundedness, closed range or compactness) then, by adjusting the spaces \(U\) and \(X\) to new spaces \(U'\) and \(X'\) (i.e., by choosing appropriate numbers \(\alpha_n\)'s and \(\beta_n\)'s), \(G: U' \rightarrow X'\) will satisfy the desired topological property. Similarly, if \(G: U \rightarrow X\) does not satisfy a desired topological property then, by adjusting the spaces \(U\) and \(X\) to new spaces \(U'\) and \(X'\), \(G: U' \rightarrow X'\) will satisfy the desired property. It is also easy to see (by using Eqs (9), (10) and (11)) that this adjustment (i.e., this choice of \(\alpha_n\) and \(\beta_n\)) can always be such that:

- only the topology of \(U\) is altered (to \(U'\)), or
- only the topology of \(X\) is altered (to \(X'\)), or
- both topologies of \(U\) and \(X\) are altered (to \(U'\) and \(X'\) respectively).

These adjustment are necessary for us to be able to use some techniques developed to solve the nonlinear control problem (2) using the fixed point of a map \(\Phi: X \rightarrow X\).

So, this structure, using matched sets for \(G: U \rightarrow X\) (or for \(G_T: U \rightarrow X'\) or \(U'\) and \(X'\)) according to the desired topological properties for \(G: U' \rightarrow X'\) (or \(G_T: U' \rightarrow X'\)) and the flexibility of the problem to let both/either \(U\) and/or \(X\) (or both/either \(U\) and/or \(X\)) to be altered.

In general, large space of functions (such as \(U = H^1\)) are not desirable since it may contain distributions. Even spaces \(U = L^2\) may sometimes be unsuitable for applications since it contains discontinuous functions. The above adjustments allow us to select spaces \(U'\) and \(X\) such that either the operator \(G\) or \(G_T\) have closed range and \(U' \approx \text{some smooth space of functions} (\text{such as } H^1 \text{ or } H^1_0)\).

Loosely speaking, the smoother we want \(U\) to be, the smoother \(X\) will have to be, that is, we shall have to restrict to smoother trajectories.
